- (57) Claim

1. A process for inactivating viruses in blood and blood products, comprising: adding phenothiazine dyes to the solutions or suspensions to be treated and subsequently irradiating said phenothiazine-dye containing solutions or suspensions with visible light in the range of the absorption peak of the respective dye, whereafter the blood or blood products may be passed over adsorbing agents for removal of the dyes, characterized in that the phenothiazine dyes are used at a concentration of from 0.1 to 2 μ M and irradiation is effected directly in transparent containers, such as blood bags, used for collecting and storing blood.

6. The process as claimed in any one of the claims 1 to 5, characterized in that said process is carried out using two containers suitable for collecting blood, such as blood bags, with a separating column interposed between said containers, and containing the adsorbing agent for the phenothiazine dyes.

(54) Title: PROCESS FOR INACTIVATING VIRUSES IN BLOOD AND BLOOD PRODUCTS		
(54) Bezeichnung: VERFAHREN ZUR INAKTIVIERUNG VON VIREN IN BLUT UND BLUTPRODUKTEN		
(57) Abstract		
<p>The invention relates to a process for inactivating viruses in blood and blood products in which phenothiazine dyes are added to the solutions or suspensions, which are then irradiated with light. The use of a very small concentration of phenothiazine dyes prevents any adverse effects on the plasma proteins. Inactivation is effected by the immediate irradiation of the blood sachet. After irradiation the dyes can be separated from the blood again by passing the blood over adsorbing agents.</p>		
(57) Zusammenfassung		
<p>Die Erfindung betrifft ein Verfahren zur Inaktivierung von Viren in Blut und Blutprodukten, bei dem die zu behandelnden Lösungen bzw. Suspensionen mit Phenothiazinfarbstoffen versetzt und anschließend mit Licht bestrahlt werden. Durch die Verwendung einer sehr geringen Konzentration an Phenothiazinfarbstoffen werden schädigende Einwirkungen auf die Plasmaproteine ausgeschlossen. Die Inaktivierung erfolgt durch unmittelbare Bestrahlung der Blutbeutel. Nach der Bestrahlung lassen sich die Farbstoffe aus dem Blut wieder abtrennen. Hierzu wird das Blut über Adsorptionsmittel geleitet.</p>		

1

PROCESS FOR INACTIVATING VIRUSES IN BLOOD
AND BLOOD PRODUCTS

5 Specification:

The invention is directed to a process for inactivating viruses
in blood and blood products, comprising: adding phenothiazine
10 dyes to the solutions or suspensions to be treated and subse-
quently irradiating said phenothiazine dye-containing solutions
or suspensions with visible light in the range of the absorp-
tion peak of the respective dye, whereafter the blood or blood
products may be passed over adsorbing agents for removal of the
dyes.

15

It is known that photodynamic substances in combination with
visible light or UV-light may have a virus inactivating effect.
This is due to the affinity of these substances to external
virus structures or to viral nucleic acid. Both facts apply to
20 phenothiazine dyes. They react with the membrane structures of
enveloped viruses and damage the same irreversibly under the
action of light, whereby the virus loses its infectiousness
(cf. Snipes, W. et al., 1979, Photochem. and Photobiol. 29,
785-790).

25

However, photodynamic substances also interact with viral RNA
or DNA, especially with the guanine residues of these nucleic
acids. When a dye/nucleic acid-complex has been formed it is
stimulated by light energy so that denaturation of the nucleic
30 acid and finally strand breakages result. Also, phenothiazine
dyes induce the conversion of molecular oxygen to oxygen radi-
cals which are highly reactive and may have various virucidal
effects (cf. Hiatt, C.W., 1972, in: Concepts in Radiation Cell
Biology, pp.57-89, Academic Press, New York; Oh Uigin et al.,
35 1987, Nucl. Acid. Res. 15, 7411-7427).

1 In contrast to other photodynamic dyes for virus inactivation,
phenothiazine dyes such as methylene blue, neutral red and
toluidine blue are of special interest because they can inacti-
vate a number of viruses already in combination with visible
5 light and, under certain conditions, even viruses that do not
possess a lipid envelope, such as adenovirus.

In addition to that, methylene blue (MB) and toluidine blue
(TB) for instance are themselves being used therapeutically,
10 among other uses also as antidotes to carbon-monoxide poisoning
and in long-term therapy of psychotic diseases. In this connec-
~~tion quantities of MB or TB much higher than those required~~
for virus inactivation are used (1 to 2 mg/kg body weight)
without any significant side effects. The low toxicities of MB
15 and TB are also substantiated by data obtained from animal ex-
periments.

However, since 1955 those of skill in the art have assumed that
dye concentrations, especially in the case of toluidine blue,
20 of less than 2.5 μM have only an insufficient virus inactivat-
ing effect (cf. F. Heinmets et al. 1955, Joint Report with the
Naval Medical Research Institute, Walter Reed Army Institute
of Research, U.S.A.).

25 In the previously described investigations of virus inactiva-
tion with phenothiazine dyes the dye concentrations are between
10 μM and 100 μM (Chang and Weinstein, 1975, Photodynamic Inac-
tivation of Herpes-virus Hominis by Methylene Blue (38524),
Proceedings of the Society for Experimental Biology and Medi-
30 cine, 148:291-293; Yen and Simon, 1978, Photosensitization of
Herpes Simplex Virus Type 1 with Neutral Red, J. gen. Virol.,
41:273-281). But at these concentrations there arises the draw-
back that not only viruses may be inactivated but also plasma
proteins, such as the coagulation factors. This is one of the
35 reasons why phenothiazine dy s have so far not achieved any
significance in the inactivation of viruses in blood and blood
products.

1 It is the object of the subject invention to provide a process
for inactivating viruses in which various kinds of viruses are
killed by the use of phen thiazine dyes without any functionally
5 detrimental effects on the plasma proteins. It is a further
object of the invention that said process be of simple design,
such that blood or blood products may be subjected to direct
treatment in commercially available blood bags and the added
dyes may be removed after processing if so desired.

10 The specified object is accomplished in accordance with the invention in that the phenothiazine dyes are used at a concentration of from 0.1 to 2 μ M and irradiation is effected directly
in transparent containers, such as blood bags, of the kind used
for the collection and storage of blood.

15 The irradiation is performed either with daylight of sufficient intensity or with monochromatic light, preferably from a cold light source at a wavelength in the range of the absorption peak of the respective dye. Also, the following conditions
20 should be observed for virus inactivation in blood plasma or plasma protein solutions: The operating temperature should be in the range of from 0 to 37°C, if possible from 4 to 20°C. The inactivating time ranges especially from 5 minutes to 5 hours, preferably from 10 minutes to 3 hours, and pH should be
25 between pH 5 and pH 9, preferably between pH 6 and pH 8.

30 An essential advantage of the process according to the invention lies in its simplicity. F. Heinmets et al. (as specified above) describes a highly complex apparatus through which, for instance, blood plasma must be passed. Here, problems of maintenance and above all capacity arise. Surprisingly, it has now been found that substantially smaller quantities of dye are sufficient and that no complex technical apparatus is required for photoinactivation.

35 Unexpectedly, it has also been found that a non-enveloped virus, such as adenovirus, which could not be inactivated under physiological conditions in plasma, could be photosensitized by

- 1 a freezing/thawing step and could thus be inactivated. In this
connection inactivation has been ascertained irrespective of
the employed order of the freezing/thawing steps and the addition
of the dye. Freezing here means a deep-freezing operation
5 at temperatures of from approximately -20°C to approximately
80K. Normally, deep-freezing is carried out at temperatures
below -30°C .

10 Virus inactivation may be carried out directly in blood or
plasma bags although these are transparent only to a limited
extent. It is merely necessary to add the dye. Then the bag inclusive
of its contents is exposed to light, whereafter the respective
product can be further processed.

- 15 Thus, the process can be carried out without any major technical
effort and is excellently suited for integration in the
processing flow of individual blood donations. The small quantity
of the dye used may either remain in the treated fluid or
may be removed by adsorbing agents.

1 Hence, the method can be carried out without any major technical effort and is excellently suited for integration in the processing flow of individual blood donations. The small quantity of the dye used may either remain in the treated fluid or
5 may be removed by adsorbing agents.

Suitable blood or blood products include:

- whole blood
- 10 - red cell concentrates
- platelet concentrates
- plasma
- serum
- cryoprecipitate
- 15 - concentrates of coagulation factors
- inhibitors
- cold insoluble globulin
- albumin.

20 Phenothiazines having the following structural formula are suitable for use in the method according to the invention:

30

	X	R ₂	R ₃	R ₁
neutral red	N	CH ₃	NH ₂	N(CH ₃) ₂
35 toluidine blue	S	CH ₃	NH ₂	N(CH ₃) ₂
methylene blu	S	H	N(CH ₃) ₂	N(CH ₃) ₂
phenothiazine	S	H	H	H

1

Example 1

5

Below, the dependence of photoinactivation on methylene blue (MB) is shown for ^{vesicular stomatitis virus} (VSV) in human plasma.

10

Varying concentrations of MB were added to human plasma containing approximately 5×10^7 Plaque Forming Units (PFU) per ml of VSV. Control samples did not contain any dye. The sample volume was 0.5 ml. One control sample and a portion of the MB containing samples were irradiated with visible light for 4 h at room temperature; the others were stored in the dark for the same length of time. The light source used was a slide projector equipped with a halogen bulb of 150 W (Osram Xenophot). The distance between the slide projector lens, i.e. the light outlet, and the samples was 30 cm in these and all further tests (with the exception of blood bag virus inactivation).

15

20

Following completion of irradiation, the virus titer was determined in all samples by means of a plaque assay. The indicator cells used were BHK cells. The test results are listed in Table 1.

25

30

35

1	Samples	MB concentr. (μ M)	Light	Virus Inactivation Factor
	contr.1	0	+	4.8
5	contr.2	0	-	1
	1	0.01	+	11.8
	2	0.1	+	28.5
	3	0.5	+	$>10^6$
	4	1	+	$>10^6$
10	5	10	+	$>10^6$
	6	50	+	$>10^6$
	7	100	+	$>10^6$
	8	1	-	1
	9	10	-	5
15	10	50	-	11.8
	11	100	-	95

Table 1: Inactivation of VSV in human plasma with and without illumination.

20 Exposure time: 4 h

The results of Table 1 show that the infectious titer of VSV was reduced by a factor of more than $6 \log_{10}$ at a minimal MB concentration of about 0.55 μ M. Significantly higher concentrations of the dye, from about 50 μ M and up, resulted in a significant reduction in the VSV titer even without exposure to light.

30 Example 2

The following test confirmed virus inactivation at low dye concentrations.

In the presence of plasma and varying amounts of methylene blue in aliquots of 500 μ l, VSV was irradiated overnight in a cold-storage room with the slide projector from a distance of 30 cm. Samples A to F were illuminated, sample G was not.

1

The results of this test are presented in Table 2. They show that under the above-mentioned conditions the VSV used was inactivated by a factor of more than $4 \log_{10}$. This required 0.5 μM of methylene blue.

5

10

It is probable that the VSV titer had already been reduced by 1 to 2 logs by the overnight incubation at 4°C , which would explain the relatively low initial titer. However, this was not simultaneously tested in our experiment.

15

A comparison of A (exposed) and G (dark) shows that light alone evidently does not influence the infectiousness of the virus to any great extent.

20

25

Sample	final MB concentr. μM	Titer/200 μl	Inactivation factor
A	0	2×10^4	2.2
B	0.01	2.4×10^4	1.8
C	0.05	2×10^4	2.2
D	0.25	3×10^2	147
E	0.5	≤ 1	$\geq 4.4 \times 10^4$
F	1.0	≤ 1	$\geq 4.4 \times 10^4$
G	0	4.4×10^4	1

30

Table 2: Virus inactivation at low dye concentrations

Example 3

35

The photoinactivation of viruses in the presence of phenothiazine dyes depends on the exposure time. To find out what exposure times would be sufficient for photoinactivation of VSV, 106 Plaque Forming Units (PFU) per ml were suspended in plasma and illuminated as described for different times at 22°C . The results are listed in Table 3. It is evident that under the

1 specified test conditions an exposure time of one hour was sufficient to reduce the infectious VSV titer by a factor of more than $6 \log_{10}$.

5	Sample	Exposure time (min)	Inactivation factor
	control	0	1
	1	5	50
10	2	30	1666 ₆
	3	60	>10 ⁶

Table 3: kinetics of the photoinactivation of VSV by MB

15

Example 4

20 A similar test was carried out in the presence of $1 \mu\text{M}$ of another phenothiazine dye, TB, instead of MB. The results listed in Table 4 show that effective inactivation of VSV can also be achieved by using TB.

25	Sample	Exposure time (min)	Inactivation factor
	control	0	1
	1	10	20
30	2	60	$>4 \times 10$ ³

Table 4: Kinetics of the photoinactivation of VSV by TB

The inactivating effect of the phenothiazine dyes was also shown for herpes simplex virus (HSV) and for type 1 human immunodeficiency virus (HIV-1).

35

1 Example 5

HSV is also inactivated in the presence of methylene blue
(1 μ M). Table 5 shows the kinetics of photoinactivation of HSV
5 by MB.

	Sample	Exposure time (min)	Inactivation factor
10	control	0	1
	1	20	35
	2	60	1500
	3	180	$>3 \times 10^4$

15 Table 5: Kinetics of the photoinactivation of
HSV by MB

20 Example 6

A similar test was conducted with the AIDS virus HIV-1. The vi-
rus titer was 6×10^2 PFU/ml. MT4-cells were used as indicator
cells. Table 6 shows that HIV-1 is apparently especially sensi-
25 tive to photoinactivation: the virus titer was already reduced
by a factor of more than 600 within the first 10 minutes.

	Sample	Exposure time (min)	Inactivation factor
30	control	0	1
	1	10	>600
	2	60	>600
	3	120	>600

35

Table 6: Kinetics of the photoinactivation of
HIV-1 by MB

Example 7

There was no success in an attempt to inactivate non-enveloped viruses under the usual physiological conditions in the presence of 80% plasma. As an example of a non-enveloped virus, adenovirus was pre-incubated for a prolonged period of time (4°C, dark) in the presence of methylene blue (MB) dye, 1 µM. Then, irradiation was effected for 30 minutes with halogen bulbs (150,000 lx). There was no change in the infectiousness of adenovirus.

Sample	Pre-Incubation time	Dye	Virus titer (log10)
control	0 h	--	6.0
1	0 h	MB	6.0
2	1 h	MB	5.5
3	4 h	MB	6.0
4	24 h	MB	6.0

Table 7: Influence of the pre-incubation time on the photosensitization of adenovirus.

The virus titer was determined as TCID50 (calculation method "Tissue Culture Infectious Dosis" by Spearman and Kaerber). The virus was titrated on FL cells (defined cell line suitable for virus titration).

When toluidine blue was used under the same experimental conditions, there was also no reduction of the virus titer that could be detected.

To achieve inactivation of adenovirus, a freeze/thaw step (F/T) with deep-freezing to -30°C was incorporated in the test run. Here, the order of F/T and the addition of the dye (1 µM MB) was of secondary importance only. The samples were again irradiated using halogen bulbs, as described above. 120,000 lx were measured.

1

	Sample Preparation of Sample	Virus Titer (log10)
5	control 7.5	
	A F/T	7.0
	B F/T + 60 min irradiation	7.5
	C F/T + MB + 60 min pre-incubation + 60 min irradiation	2.5
10	D MB + F/T	7.5
	E MB + F/T + 10 min irradiation	5.0
	F MB + F/T + 30 min irradiation	5.0
	G MB + F/T + 60 min irradiation	4.0

15 Table 8: Photosensitization of adenovirus due to an
incorporated F/T step.
Virus titration was carried out as described in Table 7.

20 Example 8

The special problem when using high dye concentrations is in
the immediate effect of these substances on plasma proteins.
Therefore, the influence of different dye concentrations on the
25 activities of coagulation factors was investigated in a further
test.

Varying amounts of MB were added to human plasma (2-ml ali-
quots). The activities of the coagulation factors V, VIII and
IX were measured immediately thereafter. As is evident from Ta-
30 ble 9, said factors are inhibited in all three cases in depen-
dence on the concentration of the dye, whereby the activities
of the factors VIII and V are inhibited from about 10 μ M and
those of factor IX already from 2.5 μ M. Consequently, at higher
concentrations MB has a direct effect on the proteins, without
need of the action of light.

1	Methylene Blue ($\mu\text{M/l}$)	Factor V E/ml	Factor VIII E/ml	Factor IX E/ml
	0	0.80	0.38	2.0
5	1	0.76	0.41	1.9
	2.5	0.78	0.41	1.6
	5	0.74	0.38	1.45
	10	0.54	0.35	1.20
	20	0.44	0.28	1.10

10

Table 9: Influence of MB on the activities of coagulation factors

15

Example 9

However, it is not only the dye concentration used but also the exposure time which influences the activities of coagulation factors. This time-dependence has been determined for varying concentrations of methylene blue.

20

Human plasma (aliquots of 2 ml) received varying amounts of MB and was then exposed to light for 1 to 4 hours (as described in Example 1). Control samples were not subjected to photo-treatment. As is evident from Table 10, the activities of the three coagulation factors V, VIII and IX are inhibited in dependence on time and the concentration of the dye. Especially in the cases of factors VIII and IX higher MB concentrations and exposure times from 2 hours upwards cause an apparent increase in their thrombolytic activities.

25

30

1	Exposure time	MB Concentra- tion $\mu\text{M/l}$	Factor V E/ml	Factor VIII E/ml	Factor IX E/ml
		0	0.86	0.33	1.20

		2.5	0.49	0.29	0.82
		10	0.42	0.27	0.64

25 Table 10: Influence of light and MB on the activities of
coagulation factors: dependence on time and MB-concentration

30 Example 10

35 In accordance with a preferred embodiment of the subject inven-
tion the photoinactivation of viruses may be effected directly
in the plasma bag. The dye at the required concentration is
merely added to the blood or the blood products and then the
bag is exposed to light. In this simpl way it is possible at
any time to treat blood products from individual donors.

1 In a test three samples of fresh human plasma were thawed. Each
sample was then inoculated with 1.5×10^6 PFU VSV within the
respective plasma bags. MB at concentrations of 1 and 10 μM ,
5 respectively, was added to two samples. A sample was taken from
the MB-free plasma and stored in the dark at 4°C as a positive
control. Then, the three bags were mounted between two Plexi-
glas plates to ensure a highly uniform layer thickness of ap-
prox. 2.5 cm. In turn, said samples were irradiated by means of
a slide projector from a distance of approx. 90 cm. After 4
10 hours, samples were taken to determine the virus titer and the
same was measured by plaque assay on FL-cells. The results
listed in Table 9 show that 1 μM MB is already sufficient to
reduce the infectious titer of VSV by a factor of more than
3log₁₀ by means of a four-hour exposure in the plasma bag. Even
15 in the absence of the dye the exposure resulted in a reduction
of the virus titer, although only by about 50%.

Sample	Exposure time (h)	MB Concentra- tion (μM)	Weight of Bag (g)	VSV Titer (PFU/ml)
control	0	0	323	5×10^3
1	4	0	323	2.5×10^3
2	4	1	289	0
25 3	4	10	257	0

Table 11: Photoinactivation of VSV in plasma bag

30 The phenothiazine dyes used for virus inactivation may remain
in the blood or the blood products, particularly at the concen-
trations used here, without side effects occurring. However,
they may be removed later by means of dialysis, gel filtration
or adsorption.

35 Of the specified methods the adsorptive ones are of main inter-
est because they require the least effort as to time and tech-
nical apparatus, and the respective plasma protein solutions
are not diluted.

However, some adsorbing agents are obviously unsuitable, such as the ion exchangers mentioned by Hiatt (Concepts in Radiation Cell Biology, pp. 57-89, Academic Press, New York, 1972) because in addition to the dye they also strongly bind plasma proteins, such as coagulation factors.

- 5 Surprisingly, it has now been found that MB and other phenothiazine dyes bind very strongly to a various commercially available separation gels, including those which either do not or only weakly bind proteins. Such adsorbing agents are therefore especially suitable for the later removal of the photo-oxidant. Of the adsorbing agents tested, the following ones may be used for the removal

10 ~~of MB and other phenothiazine dyes.~~

Adsorbing Agent	M a t e r i a l	Manufacturer or Supplier
Daltosil 75	Modified Silica Gel	Serva, Heidelberg (FRG)
Si 100-Polyol RP 18	Derivatized Silica Gel containing C ₁₈ -groups	Serva, Heidelberg (FRG)
15 Kieselgel 40	Silica Gel	Merck, Darmstadt (FRG)
Nucleosil 50 Å pore size	Silica Gel	Macherey & Nagel, Düren (FRG)
Nucleosil 100 Å pore size	Silical Gel	Macherey & Nagel, Düren (FRG)
20 Vydac SC-201 RP	Glass beads coated with Silica Gel bearing C ₁₈ -groups	Macherey & Nagel, Düren (FRG)
CPG 40	Controlled pore glass (porous glass beads)	Pierce Europe (FRG)
25 Bio beads, Amberlite adsorbent resins	Polystyrene DVB (Di-vinylbenzene), Polyacrylester	Bio Rad, München (FRG) Röhm & Haas, Frankfurt (FRG)

- 30 In most cases 2 g of the respective adsorbing agent, used as a batch, were sufficient at a feed concentration of 10 µM to completely extract the dye from a plasma protein solution.

1

Two types of adsorbing agents proved to be particularly suitable:

5

1. Silica gels having pores of so small a size (40 to approx. 100 Å diameter) that plasma proteins cannot penetrate the gel matrix while the low molecular weight dye molecules can do so and are thus bonded thereto due to ionic, electrostatic and hydrophobic interaction.

10

Examples of commercially available adsorbing agents of this type are Matrex Silica Gel (Amicon, Witten), Daltosil (Serva, Heidelberg) and Kiesel-Gel (Merck, Darmstadt).

15

2. Gels of the type based on polystyrene divinyl benzene and acrylic ester polymer, respectively. They, too, are manufactured with suitable pore sizes.

20

Examples of commercially available gels of these types are Amberlite (Röhm & Haas, Frankfurt, among others) and Bio Beads (Bio Rad, München). They are mainly used to remove non-polar substances or surface-active agents such as detergents from aqueous solutions. They are either non-polar or only slightly polar.

25

Example 11

30

Methylene blue (10 µM) was added to fresh plasma. 5-ml aliquots received varying amounts of Daltosil (pore size 75 Å) and Bio Beads SM16 (pore size 144 Å), respectively, and were then stirred for 30 minutes. Then the gel was left to settle. In the plasma the factor VIII and factor V contents, extinction at 660 nm and, for some samples, the protein contents were measured.

35

1		E (660 nm)	Protein (mg/ml)	Factor VIII (U/ml)	Factor V (U/ml)
	Fresh plasma	0.909	66.8	1.10	1.20
	Fresh plasma + MB	1.450	65.6	0.42	0.96
5	Daltosil 50 mg	0.576	—	0.60	1.05
	100 mg	0.571	—	1.10	1.10
	250 mg	0.491	—	1.10	1.20
	500 mg	0.477	66.8	1.25	1.20
10	Bio Beads				
	SM 16 50 mg	0.666	—	0.82	1.05
	100 mg	0.571	—	1.05	1.10
	250 mg	0.571	—	1.05	1.10
	500 mg	0.530	72.5	0.80	1.15

15

Table 12: Extraction of methylene blue in the bag

20 It is evident from the extinction values that apparently further substances in addition to the dye are extracted from the plasma. But these substances are not plasma proteins. The extinction values of the plasma which had been treated with 100 to 250 mg of adsorbing agent per 5 ml, i.e. with 2 to 5 weight percent (% w/v), hardly differ from those which had been extracted with 10% w/v adsorbing agent. Hence, at an MB concentration of 10 μ M 2 to 5% w/v of adsorbing agent are sufficient in both cases for removing the dye from the plasma in a batchwise operation. If the feed concentration of the dye is lower, the amount of adsorbing agent required is correspondingly lower.

25

30

Example 12

35 In a further test a 5% human serum albumin solution (5% HSA) was used instead of blood plasma. Again, the MB concentration was 10 μ M. Aliquots of 5 ml were extracted batchwise with 100 mg, respectively, i.e. 2% w/v, of the following adsorbing

1 agents for varying periods of time: Daltosil (por siz 75 A
Kiesel-Gel (pore size 40 A) and Bio Beads SM16 (pore size
144 A).

5 As Figure 1 shows, the extinction at 660 nm decreases to a con-
stant value in all three cases within a period of 20 to 30 min-
utes, i.e. this time period is sufficient to remove the photo-
oxidant in batches from a plasma protein solution. As is fur-
ther evident from Figure 1, Bio Beads SM16 and Kiesel-Gel 40
10 appear to be somewhat better adsorbing agents in the subject
case than Dalto sil with a pore size of 75 A.

Fig. 1: Adsorption kinetics of methylene blue (10 μ M) at RT
with HSA 5% 100 mg gel/5 ml HSA

Example 13

Removal of MB from plasma protein solutions by column chromatography

The aim of this test was to find out whether or not the adsorptive removal of the photo-oxidant can also be effected by chromatography. This was based on the idea of carrying out the virus inactivation by means of a dye in combination with light in a container, such as a blood bag, and in turn transferring the plasma protein solution to another container, such as a second blood bag, via a small separating column interposed between said containers, and containing the adsorbing agent. If the assembly, comprising the first bag, the adsorbing column and the second bag were prefabricated so that a closed system were available, it would be possible in a very simple way and at the minimum risk of contamination to produce virus-inactivated plasma protein preparations, including from single donor units.

To this end 250 ml of 5% albumin solution were passed at varying flow rates through a separating column containing 5 ml of Kiesel-Gel (pore size 40 Å). Fractions of 10 ml each were collected and their extinction was measured at 660 nm.

As can be seen from Table 13, the overall volume of the albumin solution could be passed through the column at flow rates of 5 and 7.5 ml/min, respectively, and no MB residues could be detected in the fractions coming off the column. Hence, the time required for removal of the dye from 250 ml of solution is only 30 to 35 minutes at most.

The test result shows that the removal of the photo-oxidant by chromatography may be effected without any problems, and also proves that the above-mentioned production of virus-inactivated plasma protein preparations from single donor units is indeed possible.

PCT/DE90/00691

PROCESS FOR INACTIVATING VIRUSES IN BLOOD
AND BLOOD PRODUCTS

Claims:

10 1. A process for inactivating viruses in blood and blood products, ~~comprising: adding phenothiazine dyes to the solutions~~ or suspensions to be treated and subsequently irradiating said phenothiazine-dye containing solutions or suspensions with visible light in the range of the absorption peak of the respective dye, whereafter the blood or blood products may be passed
15 over adsorbing agents for removal of the dyes, characterized in that the phenothiazine dyes are used at a concentration of from 0.1 to 2 μM and irradiation is effected directly in transparent containers, such as blood bags, used for collecting and storing
20 blood.

25 2. The process as claimed in claim 1, characterized in that toluidine blue or methylene blue is used as the phenothiazine dye.

30 3. The process as claimed in any one of the claims 1 or 2, characterized in that the solutions or suspensions to be treated are initially subjected to deep-freezing and are then thawed prior to irradiation.

35 4. The process as claimed in claim 3, characterized in that the dye is added prior to the deep-freezing step.

5. The process as claimed in claim 3, characterized in that the dye is added after thawing and prior to irradiation.

- 1 6. The process as claimed in any one of the claims 1 to 5,
characterized in that said process is carried out using two
containers suitable for collecting blood, such as blood bags,
with a separating column interposed between said containers,
5 and containing the adsorbing agent for the phenothiazine dyes.
7. The process as claimed in claim 6, characterized in that the
adsorbing agents used are silica gels or such agents based on
polystyrene divinylbenzene or acrylic ester polymers.
